

Vaccination guidelines for female infertility patients: a committee opinion

The Practice Committee of the American Society for Reproductive Medicine
American Society for Reproductive Medicine, Birmingham, Alabama

Encounters for infertility care are opportunities to assess and update immunization status. Women of reproductive age are often unaware of their need for immunization, their own immunization status, and the potentially serious consequences of preventable disease on pregnancy outcome. The purpose of this ASRM Practice Committee document is to summarize current recommendations regarding vaccinations for women of reproductive age. This document replaces the ASRM Practice Committee document of the same name last published in *Fertil Steril* 2008;90:S169–71. (Fertil Steril® 2012; ■ : ■ – ■ . ©2012 by American Society for Reproductive Medicine.)

Encounters for infertility care are opportunities to assess and update immunization status. Women of reproductive age often are unaware of their need for immunization, their own immunization status, and the potentially serious consequences of preventable disease on pregnancy outcome. In one study, fewer than 60% of surveyed obstetrician-gynecologists routinely obtained any vaccination history, and only 10% offered vaccines currently recommended for adults (1). National standards for vaccinations have been established and last updated in February 2012 by the Centers for Disease Control and Prevention (CDC) and are available for review on the CDC website (2). The purpose of the present document is to summarize current recommendations regarding vaccinations for female infertility patients.

VACCINATION BEFORE INFERTILITY TREATMENT AND DURING PREGNANCY

Ideally, immunizations should be completed before conception because some recommended vaccinations cannot be administered during pregnancy (1–5). Vaccinations before or during pregnancy protect women from potentially serious illnesses, prevent vertical transmission to the fetus, and confer passive immunity to the newborn. Transport of maternal immunoglobulin (IgG) antibodies to the fetus occurs throughout gestation and increases markedly during the last 4 to 6 weeks of gestation (3–5).

Many physicians are reluctant to immunize pregnant women because of concerns that a spontaneous abortion or incidental congenital anomaly might be attributed wrongly to

a vaccination. This fear persists despite the fact that there are few vaccines that are contraindicated during pregnancy (2). The contraindicated vaccines include MMR, varicella, and herpes zoster. All others are either fully recommended or recommended if some other risk factor is present. Vaccinations during pregnancy are indicated when benefits clearly outweigh risks. Special circumstances that may influence the indication for vaccination include military service, travel to high prevalence areas, hazardous occupations, immunocompromise, and chronic illness. Guidelines for vaccinations in individuals with such special indications are outlined in a committee opinion published by the Centers for Disease Control (2).

Immunizations generally recommended for women of reproductive age are listed in Table 1, which provides a condensed summary of the Recommended Adult Immunization Schedule published by the CDC. Physicians are encouraged strongly to assess the history of immunizations in women before beginning treatment for infertility.

TABLE 1

Recommended Adult Immunization Schedule modified from the Centers for Disease Control and Prevention (2).

Vaccine	Age group					
	19–21 y	22–26 y	27–49 y	50–59 y	60–64 y	≥ 65 y
Influenza*			1 dose annually [†]			
Tetanus, diphtheria, pertussis (Td/Tdap)*	Substitute 1-time dose of Tdap for Td booster; then boost with Td every 10 y [†]					Td/Tdap ^{††}
Varicella			2 doses [†]			
Human Papilloma virus (HPV),* female	3 doses [†]			No recommendation		
Human Papilloma virus (HPV),* male	3 doses ([†] 19–21; [‡] 22–26)			No recommendation		
Measles, mumps, rubella (MMR)*		1 or 2 doses [†]			1 dose [‡]	
Pneumococcal (polysaccharide)			1 or 2 doses [‡]			1 dose [†]
Meningococcal*			1 or more doses [‡]			
Hepatitis A*			2 doses [‡]			
Hepatitis B*			3 doses [‡]			

* Covered by the Vaccine Injury Compensation Program.

[†] For all persons in this category who meet the age requirements and who lack documentation of vaccination or have no evidence of previous infection.[‡] Recommended if some other risk factor is present (e.g., based on medical, occupational, lifestyle, or other indications).^{††} Tdap recommended for ≥65 if contact with <12 month old child. Either Td or Tdap can be used if no infant contact.Practice Committee. Vaccination guidelines and infertility. *Fertil Steril* 2012.

ROUTINE VACCINATIONS

Measles, Mumps, and Rubella (MMR)

MMR vaccine is recommended for all women without confirmed immunity to rubella. MMR vaccine contains live attenuated virus. Vaccination therefore should be administered before pregnancy to avoid the possibility of intrauterine infection, and pregnancy should be avoided for 1 month after vaccination. However, there is no confirmed instance where MMR vaccine has been linked to congenital malformation or significant intrauterine infection (6). Consequently, inadvertent MMR administration during pregnancy is not an indication for pregnancy termination.

Varicella

Varicella vaccine contains live attenuated virus. Prior to pregnancy, all adults without evidence of immunity should receive 2 doses of single-antigen varicella vaccine administered 1 month apart or a second dose if they have previously received only 1 dose. Pregnancy should be avoided for 1 month after vaccination. If exposed to varicella prior to pregnancy, the vaccine should be administered within 96 hours of exposure and pregnancy avoided. Pregnant women should be assessed for evidence of varicella immunity. Pregnant women who do not show signs of immunity should receive the first dose of varicella vaccine upon completion or termination of pregnancy and before discharge from the hospital. Cases of congenital varicella after immunization have been reported.

Influenza

Annual influenza vaccination is recommended for all individuals 6 months of age and older. Women who are pregnant or contemplating pregnancy should be immunized because influenza infection may increase the risk for medical complications, as heart rate, stroke volume, and oxygen consumption are increased and lung capacity is decreased during pregnancy. The optimal interval for immunization spans the months of Octo-

ber and November because the flu season occurs during January through March. Injectable influenza vaccines, trivalent inactivated vaccine (TIV), contain inactivated virus and therefore may be administered at any time during pregnancy. In contrast, intranasal influenza vaccines contain live attenuated virus and should not be administered during pregnancy.

Concerns had previously been raised about administering thimerosal-containing influenza vaccine to pregnant women. Thimerosal is a mercury-based preservative used in vaccines that was thought to be associated with adverse effects. However, no scientific evidence has correlated ill effects in the children born to women who have taken vaccines containing thimerosal (7). Therefore, the TIV influenza vaccines can be given to pregnant women whether they contain thimerosal or not.

Tetanus-Diphtheria-Pertussis (Tdap) and Tetanus-Diphtheria (Td)

A tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine (Tdap) was approved by the Advisory Committee on Immunization Practices (ACIP) in 2011 and was recommended for adults (19 to 64 years of age) who have or who anticipate having close contact with an infant less than 12 months of age (8). Due to the recent increase in pertussis outbreaks, healthcare providers should vaccinate women who are pregnant or might become pregnant and have not previously received Tdap. If they are currently pregnant, Tdap preferably should be administered during the third trimester or late second trimester (i.e., after 20 weeks' gestation). If not given during pregnancy, it should be administered immediately postpartum to ensure pertussis immunity and to reduce transmission to the newborn.

NON-ROUTINE VACCINATIONS

Pneumococcus

Pneumococcus vaccine is recommended for any person at increased risk for pneumococcal infection. Individuals at high risk include those with asplenia, sickle cell anemia, chronic

cardiovascular/pulmonary disease, diabetes, or immunocompromise as may result from human immunodeficiency virus (HIV) infection, systemic illness, or malignancy. Ideally, high-risk women should be immunized before pregnancy.

Hepatitis A (HA)

HA vaccine is recommended for any women at high risk, including those receiving clotting factor concentrates, those with chronic liver disease, women working with HA virus or HA-infected laboratory animals, women traveling to countries with a high prevalence of HA infection, and intravenous drug users. The vaccine contains inactivated virus and poses no known risk to the fetus.

Hepatitis B (HB)

HB vaccine is approved for any woman at high risk, including those receiving hemodialysis or clotting factor concentrates, healthcare workers exposed to blood and blood products, intravenous drug users, women having a sexually transmitted infection or multiple sexual partners, those traveling to countries with a high prevalence of hepatitis B infection, and women living in the same household with a known infected individual. The vaccine contains noninfectious DNA particles, can be administered during pregnancy if needed, and poses no known risk to the fetus.

Meningococcus

Meningococcus vaccine should be administered to any person who is at increased risk for meningococcal infection. For pregnant women, its use should be limited to those at high risk who have not been inoculated previously. Individuals at high risk include those who live in high endemic areas, such as sub-Saharan Africa, parts of the Middle East, and college dormitories. Preferably, such high-risk women should be vaccinated before pregnancy, because experience with the vaccine in pregnancy is limited.

SUMMARY

- Vaccination in women of reproductive age before or during pregnancy confers resistance to intrauterine infections and provides the newborn with passive immunity to neonatal infections.
- Immunization schedules are best completed before beginning treatment for infertility, because some vaccinations should not be administered during pregnancy.
- MMR and varicella immunity should be documented prior to pregnancy. If nonimmune, the vaccine should be administered and pregnancy should be avoided for 4 weeks.
- The influenza and Td immunizations should be completed before pregnancy but can be administered during pregnancy. The TIV influenza vaccine can be given anytime during pregnancy. Tdap should be given preferably during the third trimester or late second trimester.
- Varicella, pneumococcus, HA, HB, and meningococcus vaccinations are indicated in specific circumstances and are always administered best before pregnancy.

CONCLUSIONS

Prior to, during, or after pregnancy, it is important to be aware of a patient's immunization history and to update her vaccine status when appropriate.

Acknowledgments: This report was developed under the direction of the Practice Committee of the American Society for Reproductive Medicine as a service to its members and other practicing clinicians. Although this document reflects appropriate management of a problem encountered in the practice of reproductive medicine, it is not intended to be the only approved standard of practice or to dictate an exclusive course of treatment. Other plans of management may be appropriate, taking into account the needs of the individual patient, available resources, and institutional or clinical practice limitations. The Practice Committee and the Board of Directors of the American Society for Reproductive Medicine have approved this report.

The following members of the ASRM Practice Committee participated in the development of this document. All Committee members disclosed commercial and financial relationships with manufacturers or distributors of goods or services used to treat patients. Members of the Committee who were found to have conflicts of interest based on the relationships disclosed did not participate in the discussion or development of this document.

1 Vaccination guidelines for female infertility patients: a committee opinion

The Practice Committee of the American Society for Reproductive Medicine
Birmingham, Alabama

Prior to undergoing infertility treatments, vaccination guidelines should be reviewed and updated for all female patients.
